- Mainstream Technologies
 - Recognition,
 - Motion analysis,
 - Scene reconstruction,
 - Image restoration,
- Autonomous navigation : real-time localisation and mapping with one or more cameras,
- Core problem for localisation in unknown or dynamic environments.
- **Localisation:** Estimate the 6dof trajectory (3D position and orientation) of a mobile camera using visual information,
- **Mapping:** Estimate a map of the 3D environment visible to the camera(s).
- In this course we will focus on real-time i.e. < 30fps,
- Using only vision, i.e. no gyros, accelerometers, etc.,

Part 7. 6D
Localisation

The position of a point in 3D Euclidean space is defined to be relative to an **inertial Cartesian coordinate frame** so that a point $\mathbf{P} \in \mathbb{E}^3$ is identified with a point in \mathbb{R}^3 . The set of three orthonormal axes, representing a reference frame, form the basis for defining the position of a point in 3D using three coordinates as:

$$\mathbf{P} = (X, Y, Z) \in \mathbb{R}^3. \quad (1)$$

The motion trajectory of a point can be represented as a parameterized curve:

$$\mathbf{P}(t) = (X(t), Y(t), Z(t)) \in \mathbb{R}^3. \quad (2)$$

Definition

Special Euclidean Transformation and Rigid Body Motion.

A mapping $\mathbf{m} : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ satisfies the following properties:

1 *Length is preserved: $\|\mathbf{m}(\mathbf{P}_1) - \mathbf{m}(\mathbf{P}_2)\| = \|\mathbf{P}_1 - \mathbf{P}_2\|$ for all points $\mathbf{P}_1, \mathbf{P}_2 \in \mathbb{R}^3$.*

2 *The cross product is preserved:*

$\mathbf{m}_*(\mathbf{v} \times \mathbf{w}) = \mathbf{m}_*(\mathbf{v}) \times \mathbf{m}_*(\mathbf{w})$ for all vectors $\mathbf{v}, \mathbf{w} \in \mathbb{R}^3$,
where vectors transform according to

$$\mathbf{m}_*(\mathbf{v}) = \mathbf{m}(\mathbf{P}_1) - \mathbf{m}(\mathbf{P}_2).$$

*The set of all such transformations is denoted as the **special Euclidean group SE(3)**.*

Part 7. 6D
Localisation

The rotation matrix has columns mutually orthonormal, $\mathbf{R}\mathbf{R}^\top = \mathbf{R}^\top\mathbf{R} = \mathbf{I}$. The coordinate frame is chosen to be right handed such that $\det(\mathbf{R}) = +1$. The space of rotation matrices is defined by:

$$\text{SO}(3) = \left\{ \mathbf{R} \in \mathbb{R}^{3 \times 3} : \mathbf{R}\mathbf{R}^\top = \mathbf{I}, \det(\mathbf{R}) = +1 \right\}. \quad (3)$$

$\text{SO}(3) \subset \mathbb{R}^{3 \times 3}$ is called the special orthogonal group under the operation of matrix multiplication and satisfies the axioms of closure, identity, inverse and associativity. $\leftarrow (4 \times 2) \times 3 = 4 \times (2 \times 3)$

if you have a scalar (a real number) c and a matrix A that is size $m \times n$, then when you multiply A by c the resulting matrix is also of size $m \times n$.

Theorem

Any rotation \mathbf{R} can be represented as a single rotation $\theta \in [0, 2\pi)$ around a fixed axis $\mathbf{u} \in \mathbb{R}^3$.

Let θ be the angle of rotation and the unit vector

$\mathbf{u} = (u_1, u_2, u_3)^\top$ define the axis of rotation with the constraint $|\mathbf{u}| = 1$. The rotation matrix is then given by:

$$\mathbf{R} = \mathbb{I} \cos \theta + (1 - \cos \theta) \begin{bmatrix} u_1^2 & u_1 u_2 & u_1 u_3 \\ u_2 u_1 & u_2^2 & u_2 u_3 \\ u_3 u_1 & u_3 u_2 & u_3^2 \end{bmatrix} + \sin \theta \begin{bmatrix} 0 & -u_3 & u_2 \\ u_3 & 0 & -u_1 \\ -u_2 & u_1 & 0 \end{bmatrix} \quad (4)$$

A complete derivation for Euler's parametrization can be found in many textbooks on rigid-body motion and is closely related to Rodrigues' formula.

A second method is to consider rotations parameterized by α , β , γ around the principle x , y and z axes respectively. Each elementary rotation is defined by the following matrices:

$$\mathbf{R}_X(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \alpha & -\sin \alpha \\ 0 & \sin \alpha & \cos \alpha \end{bmatrix}$$
$$\mathbf{R}_Y(\beta) = \begin{bmatrix} \cos \beta & 0 & \sin \beta \\ 0 & 1 & 0 \\ -\sin \beta & 0 & \cos \beta \end{bmatrix}$$
$$\mathbf{R}_Z(\gamma) = \begin{bmatrix} \cos \gamma & -\sin \gamma & 0 \\ \sin \gamma & \cos \gamma & 0 \\ 0 & 1 & 1 \end{bmatrix},$$

Theorem

*Every rigid body motion can be realized by a **rotation** about an axis combined with a **translation** parallel to that axis.*

This parametrization of rigid motion is commonly referred to as a screw motion which can be defined by the space of **Special Euclidean** transformations:

$$SE(3) = \{ \mathbf{m} = (\mathbf{R}, \mathbf{t}) : \mathbf{R} \in SO(3), \mathbf{t} \in \mathbb{R}^3 \}. \quad (5)$$

The homogeneous representation of \mathbf{m} is then obtained in matrix form as:

$${}^a\mathbf{T}_b = \begin{bmatrix} {}^a\mathbf{R}_b & {}^a\mathbf{t}_b \\ \mathbf{0}_3 & 1 \end{bmatrix} \in \mathbb{SE}(3), \quad (6)$$

where \mathbf{T} is an equivalent representation of the **minimal vector form** $\mathbf{x} \in se(3)$.

Homogeneous Transformation

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

The infinitesimal version of rigid motion is called a **twist** where a twist represents the instantaneous velocity of a rigid body in terms of **linear** and **angular components**. A rigid body velocity is defined as a 6-dimensional twist vector $\mathbf{x} = (\mathbf{v}, \boldsymbol{\omega})$ where $\mathbf{v} = (v_x, v_y, v_z)$ is the linear component of the velocity vector and $\boldsymbol{\omega} = (\omega_x, \omega_y, \omega_z)$ the angular velocity. A twist vector is the tangent vector to an element $\mathbf{T}(t)$ of $SE(3)$.

The velocity of a point:

$${}^a\dot{\mathbf{P}}(t) = \frac{d}{dt} {}^a\mathbf{P}(t). \quad (9)$$

Rigid Body Velocity (2/2)

Andrew

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

Differentiating the point transformation:

$$\dot{^a\bar{\mathbf{P}}} = \dot{^a\mathbf{T}}_b {}^b\bar{\mathbf{P}}, \quad (10)$$

The velocity of the point with respect to the spatial reference frame a :

$$\dot{^a\bar{\mathbf{P}}} = \dot{^a\mathbf{T}}_b {}^a\mathbf{T}_b^{-1} {}^a\bar{\mathbf{P}} = \dot{^a\mathbf{T}}_b {}^b\mathbf{T}_a {}^a\bar{\mathbf{P}}, \quad (11)$$

remembering that ${}^a\mathbf{T}_b^{-1} = {}^b\mathbf{T}_a$.

The 4×4 velocity mapping in equation (11) is called a **twist** and is then easily obtained by using equation (6) as:

$$\begin{aligned} \dot{^a\mathbf{T}}_b {}^a\mathbf{T}_b^{-1} &= \begin{bmatrix} \dot{^a\mathbf{R}}_b & \dot{^a\mathbf{t}}_b \\ \mathbf{0}_3 & 0 \end{bmatrix} \begin{bmatrix} {}^a\mathbf{R}_b^\top & -{}^a\mathbf{R}_b^\top {}^a\mathbf{t}_b \\ \mathbf{0}_3 & 1 \end{bmatrix} \\ &= \begin{bmatrix} \dot{^a\mathbf{R}}_b {}^a\mathbf{R}_b^\top & -\dot{^a\mathbf{R}}_b {}^a\mathbf{R}_b^\top {}^a\mathbf{t}_b + \dot{^a\mathbf{t}}_b \\ \mathbf{0}_3 & 0 \end{bmatrix}, \end{aligned} \quad (12)$$

where $\dot{^a\mathbf{t}}_b$ is the translational velocity of a point in frame a with respect to a point in frame b .

Part 7. 6D
Localisation

The matrix $({}^a\dot{\mathbf{R}}_b {}^a\mathbf{R}_b^{-1})^\top = -{}^a\dot{\mathbf{R}}_b {}^a\mathbf{R}_b^{-1}$ is a 3×3 skew symmetric matrix mapping from \mathbb{R}^3 to \mathbb{R}^3 as:

$$[\mathbf{u}]_\times = \begin{bmatrix} 0 & -u_3 & u_2 \\ u_3 & 0 & -u_1 \\ -u_2 & u_1 & 0 \end{bmatrix}, \quad (13)$$

where the operator, $[.]_\times$, is chosen to represent a skew symmetric matrix.

The space of all skew symmetric matrices is denoted by $so(3)$:

$$so(3) = \{[\mathbf{u}]_\times \in \mathbb{R}^{3 \times 3} : \mathbf{u} \in \mathbb{R}^3\}. \quad (14)$$

Lie Algebra: $se(3)$

Therefore, there exists an operator, based on the **skew-symmetric operator** $[.]_{\times}$ for rotations, which transforms a full twist matrix to its minimal vector form defined as:

$$[\mathbf{x}]_{\wedge} = \begin{bmatrix} [\boldsymbol{\omega}]_{\times} & \mathbf{v} \\ 0 & 0 \end{bmatrix}. \quad (15)$$

The space of velocity twists can therefore be written as a 4×4 homogeneous twist matrix $[\mathbf{x}]_{\wedge}$ as:

$$se(3) = \{[\mathbf{x}]_{\wedge} \in \mathbb{R}^{4 \times 4} : [\boldsymbol{\omega}]_{\times} \in so(3), \mathbf{v} \in \mathbb{R}^3\} \subset \mathbb{R}^{4 \times 4}, \quad (16)$$

where $se(3)$ is the **Lie Algebra** of the **Lie Group $SE(3)$** .

Estimation

Part 7. 6D
Localisation

The relationship between an instantaneous twist $[{}^a\mathbf{x}]_{\wedge}$, in the spatial reference frame and an instantaneous twist $[{}^b\mathbf{x}]_{\wedge}$ in the body reference frame is obtained by homogeneous composition as:

$$\begin{aligned} \text{4x4} \rightarrow [{}^a\mathbf{x}]_{\wedge} &= {}^a\dot{\mathbf{T}}_b {}^a\mathbf{T}_b^{-1} = {}^a\mathbf{T}_b({}^a\mathbf{T}_b^{-1} {}^a\dot{\mathbf{T}}_b) {}^a\mathbf{T}_b^{-1} \\ &= {}^a\mathbf{T}_b[{}^b\mathbf{x}]_{\wedge} {}^a\mathbf{T}_b^{-1}, \end{aligned} \quad (17)$$

which gives the twist transformation matrix as:

$${}^a\mathbf{V}_b = \begin{bmatrix} {}^a\mathbf{R}_b & [{}^a\mathbf{t}_b] \times {}^a\mathbf{R}_b \\ \mathbf{0}_3 & {}^a\mathbf{R}_b \end{bmatrix}, \quad (18)$$

which is a 6×6 matrix that transforms twists from reference frame a to reference frame b . This is commonly known as the **adjoint map**.

Part 7. 6D
Localisation

The relationship between the velocity twist of a moving body and its pose:

$$\mathbf{T} = e^{[\mathbf{x}]_\wedge}, \quad (19)$$

The rotational component is found using Rodrigues formula:

$$e^{[\boldsymbol{\omega}]_\times} = \mathbb{I} + \frac{[\boldsymbol{\omega}]_\times}{\|\boldsymbol{\omega}\|} \sin \|\boldsymbol{\omega}\| + \frac{[\boldsymbol{\omega}]_\times^2}{\|\boldsymbol{\omega}\|^2} (1 - \cos(\|\boldsymbol{\omega}\|)), \quad (20)$$

The full transformation is given by:

$$e^{[\mathbf{x}]_\wedge} = \begin{bmatrix} e^{[\boldsymbol{\omega}]_\times} & \frac{(I - e^{[\boldsymbol{\omega}]_\times})([\boldsymbol{\omega}]_\times \mathbf{v}) + \boldsymbol{\omega} \boldsymbol{\omega}^\top \mathbf{v}}{\|[\boldsymbol{\omega}]_\times\|} \\ 0 & 1 \end{bmatrix}, \quad \text{if } \boldsymbol{\omega} \neq 0. \quad (21)$$

Three questions:

- 1 Correspondence geometry: Given an image point \mathbf{p} in the first image, how does this constrain the position of the corresponding point \mathbf{p} in the second image?
- 2 Camera geometry (motion): Given a set of corresponding image points $\{\mathbf{p}_i \dots \mathbf{p}_i\}, i = 1, \dots, n$, what are the camera matrices \mathbf{T} and \mathbf{T}' for the two views?
- 3 Scene geometry (structure): Given corresponding image points $\mathbf{p}_i \rightarrow \mathbf{p}'_i$ and camera matrices \mathbf{T} , \mathbf{T}' , what is the position of their 3D point \mathbf{P} in space?

Current frame 3D point $\mathbf{P} = [X, Y, Z]^\top$ and reference frame point \mathbf{P}^* are related as:

$$\mathbf{P} = \mathbf{R}\mathbf{P}^* + \mathbf{t}.$$

If \mathcal{P} lies on a plane Π gives an additional constraint:

$$\mathbf{n}^\top \mathbf{P}^* = d^* \Leftrightarrow \frac{1}{d^*} \mathbf{n} \mathbf{P}^* = 1,$$

where $\mathbf{n} \in \mathbb{R}^3$ the unit normal vector to the plane Π and $d^* \in \mathbb{R}^+$ the distance from the plane to the origin.

The overall transformation is:

$$\mathbf{P} = \left(\mathbf{R} + \frac{1}{d^*} \mathbf{t} \mathbf{n}^\top \right) \mathbf{P}^* = \mathbf{H} \mathbf{P}^*,$$

where $\mathbf{H} \in \mathbb{R}^{3 \times 3}$ is the so-called Euclidean homography matrix.

Robust
Estimation

Part 7. 6D
Localisation

The geometric transformation defines a **warping function** as:

$$\mathbf{w}(\cdot; \mathbf{G}) : \mathbb{P}^2 \mapsto \mathbb{P}^2, \quad \mathbf{p}^* \mapsto \mathbf{p} = \mathbf{w}(\mathbf{p}^*; \mathbf{G}) \propto \mathbf{G}\mathbf{p}^*.$$

The warping function has important properties:

- The **identity element** \mathbf{I} : $\mathbf{w}(\mathbf{p}; \mathbf{I}) = \mathbf{p}, \forall \mathbf{p} \in \mathbb{P}^2$;
- The **composition of two actions** corresponds to the action of the composition:

$$\mathbf{w}(\mathbf{w}(\mathbf{p}; \mathbf{G}_1); \mathbf{G}_2) = \mathbf{w}(\mathbf{p}; \mathbf{G}_1\mathbf{G}_2), \quad \forall \mathbf{p} \in \mathbb{P}^2 \text{ and } \forall \mathbf{G}_1, \mathbf{G}_2 \in \mathbb{SL}(3)$$

- The **inverse of an action** corresponds to the action of the inverse:

$$\mathbf{w}(\cdot; \mathbf{G})^{-1} = \mathbf{w}(\cdot; \mathbf{G}^{-1}), \quad \forall \mathbf{G} \in \mathbb{SL}(3)$$

Localisation

- Constrain $\det(\mathbf{H} = 1)$ so that \mathbf{H} belongs the *Special Linear* $\text{SL}(3)$ group.
- The $\text{SL}(3)$ is a Lie group and $\mathfrak{sl}(3)$ its Lie algebra.
- The elements of $\mathfrak{sl}(3)$ are 3×3 matrices of null trace.

$\{\mathbf{A}_1, \mathbf{A}_2, \dots, \mathbf{A}_8\}$ is a basis of $\mathfrak{sl}(3)$. Any matrix $\mathbf{A}(\mathbf{x}) \in \mathfrak{sl}(3)$ is a linear combination of the basis:

$$\mathbf{A}(\mathbf{x}) = \sum_{i=1}^8 x_i \mathbf{A}_i, \quad (22)$$

with $\mathbf{x} = [x_1, x_2, \dots, x_8]^\top \in \mathbb{R}^8$ the minimal vector.

The exponential map is determined as:

$$\mathbf{G}(\mathbf{x}) = \exp(\mathbf{A}(\mathbf{x})) = \sum_{i=0}^{\infty} \frac{1}{i!} (\mathbf{A}_i(\mathbf{x}))^i. \quad (23)$$

Localisation

Consider now a region-of-interest $\mathcal{R}^* \subseteq \mathcal{I}^*$ of a planar region of an image.

If the true homography $\bar{\mathbf{H}}$ is known then we have the following relation:

$$\bar{\mathbf{p}}^* = w(\bar{\mathbf{H}}\bar{\mathbf{p}}^*) = [u, v, 1]^\top \quad \forall \mathbf{p}^* \in \mathcal{R}^*$$

- Note that the warping function serves to normalise the homogeneous coordinate to 1.
- The set of transformed points is in general *scattered* after warping meaning that the transformed points don't correspond to a regular image grid. We will re-visit this when transforming images.

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

Consider a line in each images back projecting onto 3 planes:

$$\pi = \mathbf{P}^T \mathbf{l} = \begin{pmatrix} \mathbf{l} \\ 0 \end{pmatrix}$$

$$\pi' = \mathbf{P}'^T \mathbf{l}' = \begin{pmatrix} \mathbf{A}^T \mathbf{l}' \\ \mathbf{a}_4^T \mathbf{l}' \end{pmatrix}$$

$$\pi'' = \mathbf{P}''^T \mathbf{l}'' = \begin{pmatrix} \mathbf{B}^T \mathbf{l}'' \\ \mathbf{b}_4^T \mathbf{l}'' \end{pmatrix}$$

remembering that:

- $\mathbf{P} = [\mathbf{A} \ \mathbf{a}]$ bec. they are up to transformations
- \mathbf{A} and \mathbf{B} are the infinite homographies from the 1st to the 2nd and 3rd cameras resp.
- \mathbf{a} and \mathbf{b} are the epipoles arising from projecting 1st and 2nd camera centers resp.

Three View Geometry - Trifocal tensor

Andrew
Comport

Part 1.

Part 2.
Applications

Part 3. Rigid
Body Motion

Part 4. Image
formation

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

The intersection constraint among image lines is obtained by analysing the points that lie on the line of intersection which are linearly dependent:

$$\mathbf{X} = \alpha \mathbf{X}' + \beta \mathbf{X}''$$

Which means that the $\det(\mathbf{M}) = 0$ and \mathbf{M} must be rank 2:

$$\mathbf{M} = [\pi_1, \pi', \pi''] = \begin{bmatrix} \mathbf{I} & \mathbf{A}^\top \mathbf{l}' & \mathbf{B}^\top \mathbf{l}'' \\ \mathbf{0} & \mathbf{a}_4^\top \mathbf{l}' & \mathbf{b}_4^\top \mathbf{l}'' \end{bmatrix}$$

The linear dependence means that:

grouping the terms

$$\pi = \alpha\pi' + \beta\pi''$$

and since the bottom left hand element is 0 it follows that

$\alpha = k(\mathbf{b}_4^\top \mathbf{l}'')$ and $\beta = -k(\mathbf{a}_4^\top \mathbf{l}')$.

Three View Geometry - Trifocal tensor

Andrew

Part 1.
Introduction

Part 2.
Applications

Part 3. Rigid
Body Motion

Part 4. Image
formation

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

Applying this to the top row of \mathbf{M} gives:

$$\begin{aligned}\mathbf{l}' &= (\mathbf{b}^\top \mathbf{l}'') \mathbf{A}^\top \mathbf{l}' - (\mathbf{a}_4^\top \mathbf{l}') \mathbf{B}^\top \mathbf{l}'' \\ &= (\mathbf{l}''^\top \mathbf{b}_4) \mathbf{A}^\top \mathbf{l}' - (\mathbf{l}'^\top \mathbf{a}_4) \mathbf{B}^\top \mathbf{l}''\end{aligned}$$

For each row \mathbf{a}_i and \mathbf{b}_i gives the matrix i of the trifocal tensor:

i: tensor notation $\mathbf{T}_i = \mathbf{a}_i \mathbf{b}_4^\top - \mathbf{a}_4 \mathbf{b}_i^\top$

and the incidence relation can be written:

and now this gives the relation
between the other two lines
and the first line which is in the
world's frame

$$\mathbf{l}_i = \mathbf{l}'^\top \mathbf{T}_i \mathbf{l}''$$

The set of three matrices $\mathbf{T}_1, \mathbf{T}_2, \mathbf{T}_3$ constitute the trifocal tensor in matrix notation.

Localisation

Consider now a region-of-interest $\mathcal{R}^* \subseteq \mathcal{I}^*$ in the reference image.

If the true homography $\bar{\mathbf{H}}$ is known then we have the following relation:

$$\mathcal{I}^* = \mathcal{I}(w(\mathbf{p}^*, \mathbf{H})) \quad \forall \mathbf{p}^* \in \mathcal{R}^*$$

where $\mathcal{I}(\mathbf{p})$ refers to an interpolation (bi-linear or cubic) of the current image at $\mathbf{p} = \mathbf{w}(\mathbf{p}^*; \mathbf{H}) = [u, v, 1]^\top$ since there is rarely a one-to-one pixel correspondence between pixels in each image.

Note that the intensity warping function also inherits the geometric properties.

- Taylor series expansion of $\mathbf{e}(\mathbf{x})$:

$$\mathbf{e}(\mathbf{x}) = \mathbf{e}(\mathbf{0}) + \mathbf{J}(\mathbf{0})\mathbf{x} + \frac{1}{2}\mathbf{M}(\mathbf{0}, \mathbf{x})\mathbf{x} + \mathbf{O}(\|\mathbf{x}\|^3)$$

where

$\mathbf{J}(\mathbf{x}) = \nabla_{\mathbf{x}}\mathbf{e}(\mathbf{x})$ is the Jacobian matrix of dimension $n \times n$

and

$\mathbf{M}(\mathbf{x}_1, \mathbf{x}_2) = \left[\begin{array}{ccc} \frac{\partial^2 \mathbf{e}_1(\mathbf{x}_1)}{\partial \mathbf{x}_1^2} \mathbf{x}_2 & \dots & \frac{\partial^2 \mathbf{e}_n(\mathbf{x}_1)}{\partial \mathbf{x}_1^2} \mathbf{x}_2 \end{array} \right]^T$ composed of
 $n \times n$ Hessian matrices of size $n \times n \times 6$.

- Solve iteratively by gradient descent.

Robust
Estimation

Part 7. 6D
Localisation

- The motion of a 3D point is modeled by:

$$\dot{\mathbf{P}} = \boldsymbol{\omega} \times \mathbf{P} + \mathbf{v} \quad (25)$$

- Differentiating the perspective projection $\mathbf{p} = \frac{f}{Z}\mathbf{P}$ gives:
3D point

rate of change of pixel → $\dot{\mathbf{p}} = \frac{1}{\lambda}\dot{\mathbf{P}} - \frac{\lambda}{\lambda}\mathbf{p}, \quad \lambda = \frac{Z}{f}$ (26)

- Substituting (25) into (26), the image Jacobian is then:

$$\mathbf{J} = \begin{bmatrix} \text{v (linear velocity)} & \text{w (rotational velocity)} \\ \begin{bmatrix} \frac{f}{Z} & 0 & -\frac{x}{Z} \\ 0 & \frac{f}{Z} & -\frac{y}{Z} \end{bmatrix} & \begin{bmatrix} -\frac{xy}{f} & \frac{f^2+x^2}{f} & y \\ \frac{(f^2+y^2)}{f} & \frac{xy}{f} & x \end{bmatrix} \end{bmatrix} \quad (27)$$

pixel $\mathbf{p}(\text{dot}) = \mathbf{J} * [\mathbf{v} \ \mathbf{w}]'$

only the linear velocity depends on the 3d point while the rotational one does not

Non-linear Estimation - Newton

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

- 1 Draw N subsamples $\mathbf{s}_J, J = 1 \dots N$ of d independent visual features. The maximum number of subsamples is $N_{\max} = \binom{nm}{d}$, therefore if nm is large N_{\max} may be very large!
- 2 For each subsample \mathbf{s}_J , the unknown parameters \mathbf{x}_J are computed according to:

$$\mathbf{x}_J = -\mathbf{J}_{\mathbf{s}_J}^+(\mathbf{e})$$

- 3 For each \mathbf{x}_J , the median of square residuals is determined, denoted M_J , with respect to the whole set of features:

$$M_J = \text{Med}_{i=1 \dots n} (\mathbf{J}_{\mathbf{s}_i} \mathbf{x}_J + (e_i))^2$$

- 4 The minimal value M^* is retained amongst all $N M_J$'s along with each corresponding \mathbf{x}_J .

■ 2D Tracking

■ Pros

- Good for learning in unknown environments,
- Can be used where little prior information is available,
- Local tracking methods are efficient,
- Low level elements are flexible to manipulate within Bayesian frameworks.

■ Cons

- No 3D information available,
- 3D occlusions difficult to handle,
- Imprecision in position estimation,
- Little resistance to external noise.

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

■ Goal:

- Estimate the pose $\mathbf{T} \in SE(3)$ of an object with respect to the camera frame.
- Example for point features:

- Minimizing the error between the observation and the projection of the model in the image:

$$\hat{\mathbf{T}} = \operatorname{argmin}_{\mathbf{T}} \sum_i (\mathbf{p}^* - \pi(\mathbf{TP}))^2$$

where \mathbf{P} are the coordinates of the same points in the object frame.

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

- The objective is to minimize the error:

$$\mathbf{e} = (\mathbf{s}(\mathbf{x}(t)) - \mathbf{s}^*) = (\pi(\mathbf{x}(t), \xi, \mathbf{P}) - \mathbf{s}^*)$$

where

- \mathbf{s}^* is the desired value of the visual features in the image,
- $\mathbf{s}(\mathbf{x}(t))$ is the current value of the features for the pose $\mathbf{T}(\mathbf{x})$.
- The error is related to the camera velocity twist $\dot{\mathbf{x}}$ by derivation using a first order Taylor series expansion:

$$\dot{\mathbf{s}} = \mathbf{J}_s \dot{\mathbf{x}},$$

where the Jacobian matrix \mathbf{J} depends on the type of visual features \mathbf{s} .

Control Law

formation

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

- Iterative minimization of the error by and exponential decrease:

$$\dot{\mathbf{e}} = -\lambda \mathbf{e}$$

- The control law which regulates the error $\mathbf{e} \rightarrow 0$ is given by:

$$\mathbf{x} = -\lambda \mathbf{J}_s^+ (\mathbf{s}(\mathbf{x}) - \mathbf{s}^*)$$

- After convergence the new pose is updated as:

$$\mathbf{T} = e^{[\mathbf{x}]^\wedge} \mathbf{T}$$

- where \mathbf{T} is the homogeneous representation of the pose vector \mathbf{x} and $e^{[\mathbf{x}]^\wedge}$ is the exponential map of a twist to is pose representation.

formation

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

- **Stability** of the non-linear minimisation can be shown if the following criterion is true:

$$\hat{\mathbf{J}}_{\mathbf{s}}^+ \hat{\mathbf{J}}_{\mathbf{s}}^+ > 0, \forall t,$$

- The choice of $\mathbf{J}_{\mathbf{s}}$ is important and different choices are possible:

- 1 **At solution**: Calculated with the final estimate of the pose and image features:

$$\hat{\mathbf{J}}_{\mathbf{s}}^+ = \hat{\mathbf{J}}_{\mathbf{s}}^+(\mathbf{s}^*, \mathbf{x}^*)$$

- 2 **Forward compositional**: Calculated with the current estimate of the pose and image features:

$$\hat{\mathbf{J}}_{\mathbf{s}}^+ = \hat{\mathbf{J}}_{\mathbf{s}}^+(\mathbf{s}^*(\mathbf{x}(t)))$$

- 3 **Inverse compositional**: Calculated with the initial estimate of the pose and final or initial image features:

$$\hat{\mathbf{J}}_{\mathbf{s}}^+ = \hat{\mathbf{J}}_{\mathbf{s}}^+(\mathbf{s}(0), \mathbf{x}(0))$$

$$\hat{\mathbf{J}}_{\mathbf{s}}^+ = \hat{\mathbf{J}}_{\mathbf{s}}^+(\mathbf{s}^*, \mathbf{x}(0))$$

Localisation

Edges

- Regions of strong position information [Haralick81, Canny83],
- Efficient 1D search along the normal,
- Convolution efficiency,
- Invariant to illumination changes,

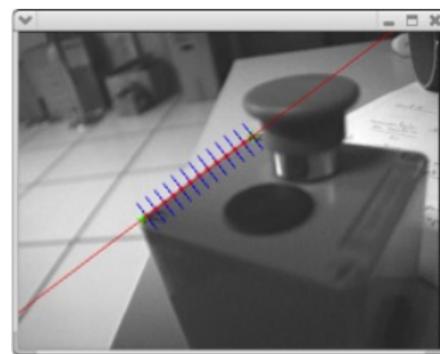

Maximum Likelihood Framework [Bouthemy89]

- Model edges as spatio-temporal patches,
- Oriented edge masks,
- Sub-pixel precision.

Scale Invariant Edges

- Propagating likelihood pose estimation.
- No detection threshold needed.
- Handle edges with varying strength.

Localisation

- Robust iteratively re-weighted least squares:
 - M-estimation and
 - Iteratively Re-weighted Least Squares (IRLS),
 - Uses all data and works better with the entire image.
- The optimisation equation which minimizes $(\mathbf{s} - \mathbf{s}^*)$ is given by:

$$\mathbf{x} = -\lambda(\mathbf{DJ})^+(\mathbf{s} - \mathbf{s}^*)$$

- where

$$\mathbf{D} = \begin{bmatrix} w_1 & & 0 \\ & \ddots & \\ 0 & & w_n \end{bmatrix}$$

Part 7. 6D
Localisation

- Planar target tracking problem in a video stream (small inter-frame motion).
- Use planar patch warping to define an error to optimise (inverse compositional):

$$\mathbf{e} = \mathcal{I} \left(w \left(\mathbf{p}^*; \hat{\mathbf{H}}\mathbf{H}(\mathbf{x}) \right) - \mathcal{I}^*(\mathbf{p}^*) \right)$$

The error is minimised using a least squares optimisation criterion:

$$O(\mathbf{x}) = \arg \min_{\mathbf{x}} \sum_{\mathbf{p}_i^* \in \mathcal{R}^*} (\mathbf{e}_i)^2$$

Part 7. 6D
Localisation

- Solved iteratively for \mathbf{x} by performing a Taylor series expansion of the cost function.
- Reference Jacobian computed once.
- Estimate obtained with a pseudo-inverse of the Jacobian Matrix $\mathbf{J}^+ = (\mathbf{J}^\top \mathbf{J})^{-1} \mathbf{J}$:

$$\hat{\mathbf{x}} = \mathbf{J}^+ \mathbf{e}$$

where $\mathbf{J} = \mathbf{J}_{\mathcal{I}} \mathbf{J}_w \mathbf{J}_x$ is the reference Jacobian matrix decomposed into the spatial image intensity gradient $\mathbf{J}_{\mathcal{I}}$, the geometric warping gradient \mathbf{J}_w and the gradient of the homography with respect to its Lie algebra parametrisation \mathbf{J}_x .

- The planar homography update:

$$\hat{\mathbf{H}} \leftarrow \hat{\mathbf{H}} e^{(\mathbf{A}(\mathbf{x}))}.$$

- Convergence is stopped at a predetermined threshold $|\mathbf{x}|$ or $|\mathbf{e}|$, whichever comes first.

■ Computer vision community:

- Structure from motion,
- 3D model reconstruction,
- Bundle adjustment over long sequences.

An old example from Oxford's Visual Geometry Group [Torr,
Zisserman]

Sequential real-time processing

- Simultaneous Localisation and Mapping (SLAM)
- Building a long-term map by propagating and correcting uncertainty,
- Mostly used in simplified 2D environments with specialised sensors such as laser range-finders, gps, sonars, etc...
- Robotic community:
 - Probabilistic approaches have been studied extensively
 - For example: work of Durrant-Whyte and Thrun.
 - Primarily aimed at autonomous robots, often slow moving with additional control input, e.g. odometry

Part 7. 6D
Localisation

- The predictor-corrector framework enables active tracking of features.
- Measurement uncertainty regions derived from the filter constrain the search for matching features
 - reduces image processing operations: real-time performance
- Contrast with detection methodologies - detect all potential features and find best set of matches with previous frame (e.g. using optimisation, RANSAC, etc).
- NB: as uncertainty in camera pose increases: search regions increase → detection + matching takes over.

■ Time Update

- 1 Project the state ahead:

$$\hat{\mathbf{x}} = f(\hat{\mathbf{x}}, \mathbf{u})$$

- 2 Project the error covariance ahead:

$$\mathbf{P}_{new} = \frac{\partial f}{\partial \mathbf{x}} \mathbf{P} \frac{\partial f^T}{\partial \mathbf{x}} + \mathbf{Q}$$

where \mathbf{Q} is the additive process noise.

■ Measurement Update

covariance matrix tells us, how cer-
tain we are for a certain pose, forex-
ample

- 1 Make measurement z to give the innovation ν

$$\nu = z - \hat{h}\hat{x} \text{ gives } u \text{ the predicted measure-} \\ \text{ment}$$

- 2 Calculate innovation covariance S and Kalman gain W

$$S = \frac{\partial h}{\partial x} P \frac{\partial h}{\partial x}^T + R \\ W = P \frac{\partial h}{\partial x}^T S^{-1}$$

- 3 Update estimate and error covariance:

$$\hat{x}_{\text{new}} = \hat{x} + W\nu \\ P_{\text{new}} = P - WSW^T$$

Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

- A new feature has unknown depth

- 1 **Populate the line with 100 particles, spaced uniformly between 0.5m and 5m from the camera.**
- 2 Match each particle in successive frames **to find probability of that depth.**
- 3 When depth covariance is small, convert to Gaussian.

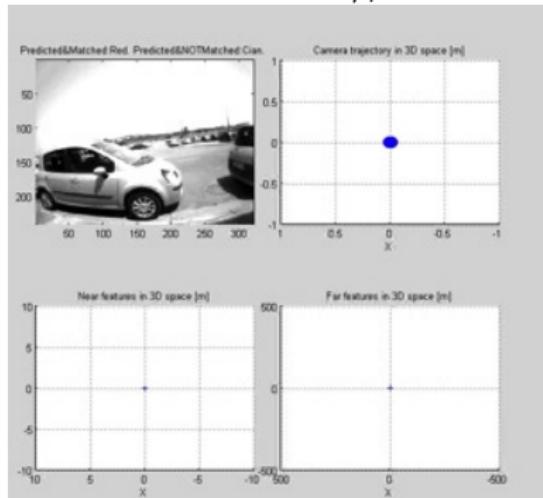

Inverse depth parametrisation

A scene 3D point \mathbf{P}_i is defined by the state vector:

$$\mathbf{y}_i = \begin{pmatrix} x_i & y_i & z_i & \theta_i & \phi_i & \rho_i \end{pmatrix}^\top$$

which models a 3D point located at:

$$\begin{pmatrix} x_i & y_i & z_i \end{pmatrix}^\top + \frac{1}{\rho_i} m(\theta_i, \phi_i)$$

■ Feature based [Nister04, Royer04] :

- Real large scale scenes,
- Difficult to model all features: usually point feature based,
- Propagates feature extraction uncertainty to pose estimation,
- Often have a temporal feature matching step,
- Require corrective techniques such as EKF and Bundle adjustment.

Direct 3D Tracking

Andrew

Robust
Estimation

Part 7. 6D
Localisation

- Intensity-based direct method [Silveira, Malis, Rives]

$$\arg \min_{\hat{\mathbf{x}} \in \mathbb{R}^6} \frac{1}{2} \sum_{\mathbf{p}_i \in \mathbb{R}^+} \left[\mathcal{I}(w(\mathbf{p}_i^*; \mathbf{G}(\hat{\mathbf{T}}\mathbf{T}(\tilde{\mathbf{x}}))) - \mathcal{I}^*(\mathbf{p}_i^*) \right]^2$$

where

$$\mathbf{G}(\mathbf{T}; \mathbf{n}^*) = \mathbf{K} \frac{\mathbf{R} + \mathbf{t}\mathbf{n}^\top}{\sqrt[3]{1 + \mathbf{t}^\top \mathbf{R}\mathbf{n}^*}} \mathbf{K}^{-1}$$

■ Pros

- Accurate, efficient and robust,
- No local matching, only SLAM,
- Full 3D deformation of planar image patches (i.e. no erroneous point detection)

■ Cons

- Planar Homography assumption must detect planar regions,
- Unknown Scale factor

Estimation

Part 7. 6D
Localisation

- Quadrifocal geometry allows definition of two trifocal tensors:

$$\mathcal{T}_i^{jk} = \mathbf{k}'_m^j \mathbf{r}'_n^m \mathbf{k}^{-1}_i^n \cdot \mathbf{k}''_o^k \mathbf{t}'''_o(t) - \mathbf{k}'_p^j \mathbf{t}'^p \cdot \mathbf{k}''_q^k \mathbf{r}''_r^q(t) \mathbf{k}^{-1}_i^r,$$

- Each trifocal tensor defines an image transfer of points in the reference pair to points in another pair of images:

$$\begin{bmatrix} \mathbf{p}''^k \\ \mathbf{p}'''^n \end{bmatrix} = \begin{bmatrix} \mathbf{p}^i \mathbf{l}'_j \mathcal{T}_i^{jk} \\ \mathbf{p}''^l \mathbf{l}_m \mathcal{T}_l^{mn} \end{bmatrix},$$

- This warping operator is a $\mathbb{SE}(3)$ group *action*.

Estimation

Part 7. 6D
Localisation

- Efficient second order approximation:

$$\mathcal{J}(\tilde{\mathbf{x}}) \approx \mathcal{J}(\mathbf{0}) + \frac{\mathcal{J}(\mathbf{0}) + \mathcal{J}(\tilde{\mathbf{x}})}{2} \tilde{\mathbf{x}} + \mathcal{R}(\|\tilde{\mathbf{x}}\|^3),$$

- Second Order approximation using the current and reference images:

(requires the warping function to be a group action):

$$\mathcal{J}(\tilde{\mathbf{x}}) = \frac{(\mathbf{J}_{\mathcal{I}} + \mathbf{J}_{\mathcal{I}^*})}{2} \mathbf{J}_w \mathbf{J}_T \mathbf{J}_{\mathcal{V}},$$

- Robust ESM minimisation is solved iteratively :

$$\tilde{\mathbf{x}} = -\lambda (\mathbf{D}\mathcal{J})^+ \mathbf{D}(\mathcal{I} - \mathcal{I}^*),$$

Part 7. 6D
Localisation

Direct 3D Model-based (MB) tracking

The unknown 3D motion \mathbf{x} between an augmented reference image $\mathcal{S} = \{\mathcal{I}^*, \mathcal{P}\}$ and the current camera \mathcal{I}_t can be iteratively estimated by minimising a robust error between the warped image and the reference image:

$$\mathbf{e}_{MB} = \rho \left(\mathcal{I}_t \left(w(\mathcal{P}; \widehat{\mathbf{T}}\mathbf{T}(\mathbf{x})) \right) - \beta_{MB} - \mathcal{I}^*(\mathcal{P}) \right).$$

Dynamic environments - illumination change

- *Global* illumination - $\beta_{MB} = Median(\mathbf{e}_{MB})$ [?].
- *Local* illumination - robust diagonal weighting matrix \mathbf{D} [?].

Inconvenient: Large environment changes

Visual odometry(VO) tracking

Andrew
Comport

Part 1.
Introduction

Part 2.
Applications

Part 3. Rigid
Body Motion

Part 4. Image
formation

Part 5. 3D
Visual
Geometry

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

A non-classic visual odometry approach - improves convergence speed and robustness to dynamic changes (current and previous image intensities are minimised with model geometry).

$$\mathbf{e}_{vo} = \rho \left(\mathcal{I}_t(w(\mathcal{P}; \widehat{\mathbf{T}}\mathbf{T}(\mathbf{x}))) - \beta_{vo} - \mathcal{I}_{t-1}^w(\mathcal{P}) \right),$$

Advantages

- 3D geometry is shared with the original 3D model.
- Very small local illumination changes can be expected between successive frames (ie. $\geq 20\text{Hz}$) \Rightarrow fast convergence.
- Still robust to global illumination changes (due to the global bias model).

however **visual odometry drifts** with time.

Hybrid model-based and visual odometry (H) tracking

Part 5.2 Image
synthesis and
Image warping

Part 6.
Non-linear
Robust
Estimation

Part 7. 6D
Localisation

Proposed method: Global minimisation of the error functions, combines the advantages of both techniques.

$$\mathbf{e}_H = [\mathbf{e}_{MB} \quad \mathbf{e}_{VO}]^T.$$

- **Fast** convergence (due to VO).
- **No drift** since raw sensor measurement is maintained in the minimisation process (due to MB).
